Construction of  
computably random  
sets

---

Some extension

---

Construction of  
Schnorr random sets

---

# Introduction

# Goal

The goal of this talk is to give a proof idea of separation between

- (i) computable randomness and ML-randomness,
- (ii) Schnorr randomness and computable randomness.

These are basic facts in the theory of algorithmic randomness.

# *Random*

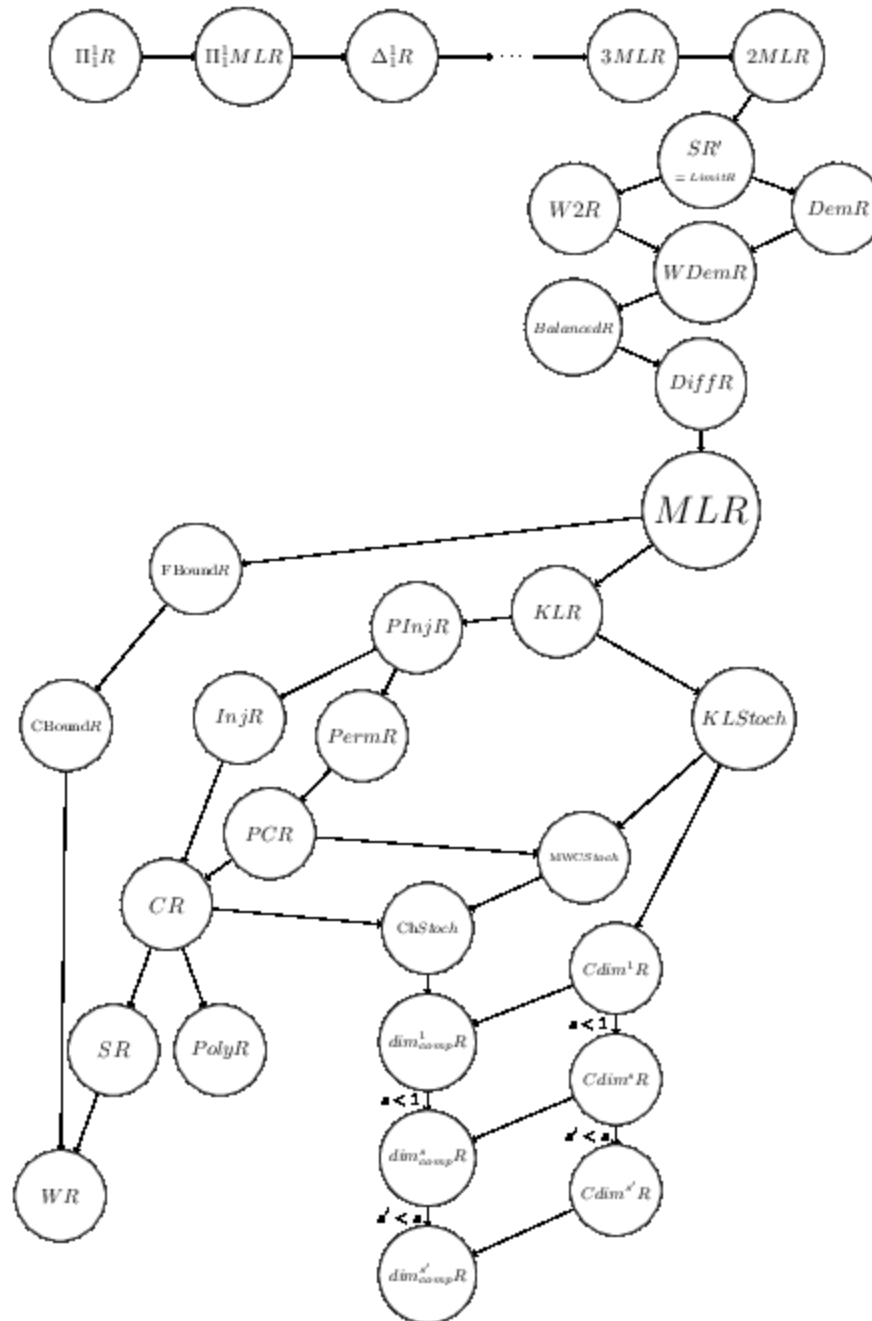

$X$ : an infinite binary sequence or a set of natural numbers

010010110100100110101000101100010101011101001...

Seems **random**, but what mean?

# Randomness Zoo

Antoine Thiery

# *Randomness notions*

**SR**: the class of Schnorr random sets

**CR**: the class of computably random sets

**MLR**: the class of Martin-Löf random sets

$$\text{SR} \supsetneq \text{CR} \supsetneq \text{MLR}$$

The first task is to separate the notions.

$2^\omega$

**SR**

**CR**

**MLR**

# Martingale

A (super)martingale is a function  $M : 2^{<\omega} \rightarrow \mathbb{R}^+$  such that

$$M(\sigma) = (\geq) \frac{M(\sigma 0) + M(\sigma 1)}{2}$$

for all  $\sigma \in 2^{<\omega}$ .

This is called the **fairness condition**.  $M$  is a capital process and the average should be the same as the previous amount.

$x \in \mathbb{R}$  is **comp.** if  $\exists (a_n)_n \in \mathbb{Q} : \text{comp. s.t. } |a_n - x| < 2^{-n}$ .

$x \in \mathbb{R}$  is **left-c.e.** if  $\exists (a_n)_n \uparrow \in \mathbb{Q} : \text{comp. s.t. } \lim_n a_n = x$ .

$f : 2^{<\omega} \rightarrow \mathbb{R}^+$  is comp. or left-c.e. if so is  $f(\sigma)$  uniformly.

# Definition

$X \in 2^\omega$  is **ML-random** if  $\sup_n M(X \upharpoonright n) < \infty$  for each left-c.e. martingale  $M$ .

$X$  is **computably random** if  $\sup_n M(X \upharpoonright n) < \infty$  for each computable martingale  $M$ .

$X$  is **Schnorr random** if  $M(X \upharpoonright n) < f(n)$  a.a. for each comp. mart.  $M$  and each comp. order  $f$ .

Random if the capital by any betting strategy is bounded.

# Goal

**Theorem 1** (Nies-Stephan-Terwijn 2005). *The following are equivalent.*

- (i)  *$A$  is high.*
- (ii) *There is a set  $B \equiv_T A$  that is computably random but not ML-random.*
- (iii) *There is a set  $C \equiv_T A$  that is Schnorr random but not computably random.*

### Construction of Schnorr random sets

# Construction of computably random sets

# Enumerability

**Observation 2.** *We can computably enumerate all left-c.e. martingales.*

*So there exists a universal left-c.e. martingale.*

*We can not computably enumerate all computable martingales.*

*We can computably enumerate all partial computable martingales.*

Object

Enumerability

partial comp. func.

Yes

total comp. func.

No

left-c.e. mart.

Yes

partial comp. mart.

Yes

comp. mart.

No

# ***ML-randomness***

**Proposition 3.** *There exists a ML-random set.*

*Proof.* For a universal martingale  $M$ , construct a set  $X$  so that

$$\sigma_{n+1} = \sigma_n a, \quad a \in \{0, 1\},$$

$$M(\sigma_n) \geq M(\sigma_{n+1}),$$

$$\sigma_n \preceq \sigma_{n+1} \prec X.$$

With a little trick,

$$X \leq_T M \leq_T \emptyset'$$

# Computable randomness

**Proposition 4.** *There exists a computably random set that is not ML-random.*

We need a more delicate method.

- (i) Construct a martingale  $M$  that multiplicatively dominates all computable martingales.
- (ii) Construct a computably random set  $X$  from  $M$ .
- (iii) Construct another martingale  $N$  that succeeds along  $X$ .

# 1st try

Define a martingale  $M$  by

$$M = \sum_e 2^{-e} M_e$$

where  $\{M_e\}$  is a non-effective enumeration of all computable martingales.

Define a set  $X$  so that  $M$  does not increase along  $X$ . By the non-effectiveness, the Turing degree of  $M$  cannot be bounded and  $X$  may be really complicated.

## *2nd try, enumerate*

Define a supermartingale  $M$  by

$$M = \sum_e 2^{-e} M_e$$

where  $\{M_e\}$  is a uniform sequence of all partial computable martingales.

Define a set  $X$  so that  $M$  does not increase along  $X$ .  
To compute  $X \upharpoonright n$ , it suffices to know which  $M_e(\sigma)$  is defined.

The number of  $\sigma$  is bounded but not small.

The number of  $e$  is unbounded.

# Unite

$M$ : a (maybe partial) computable martingale

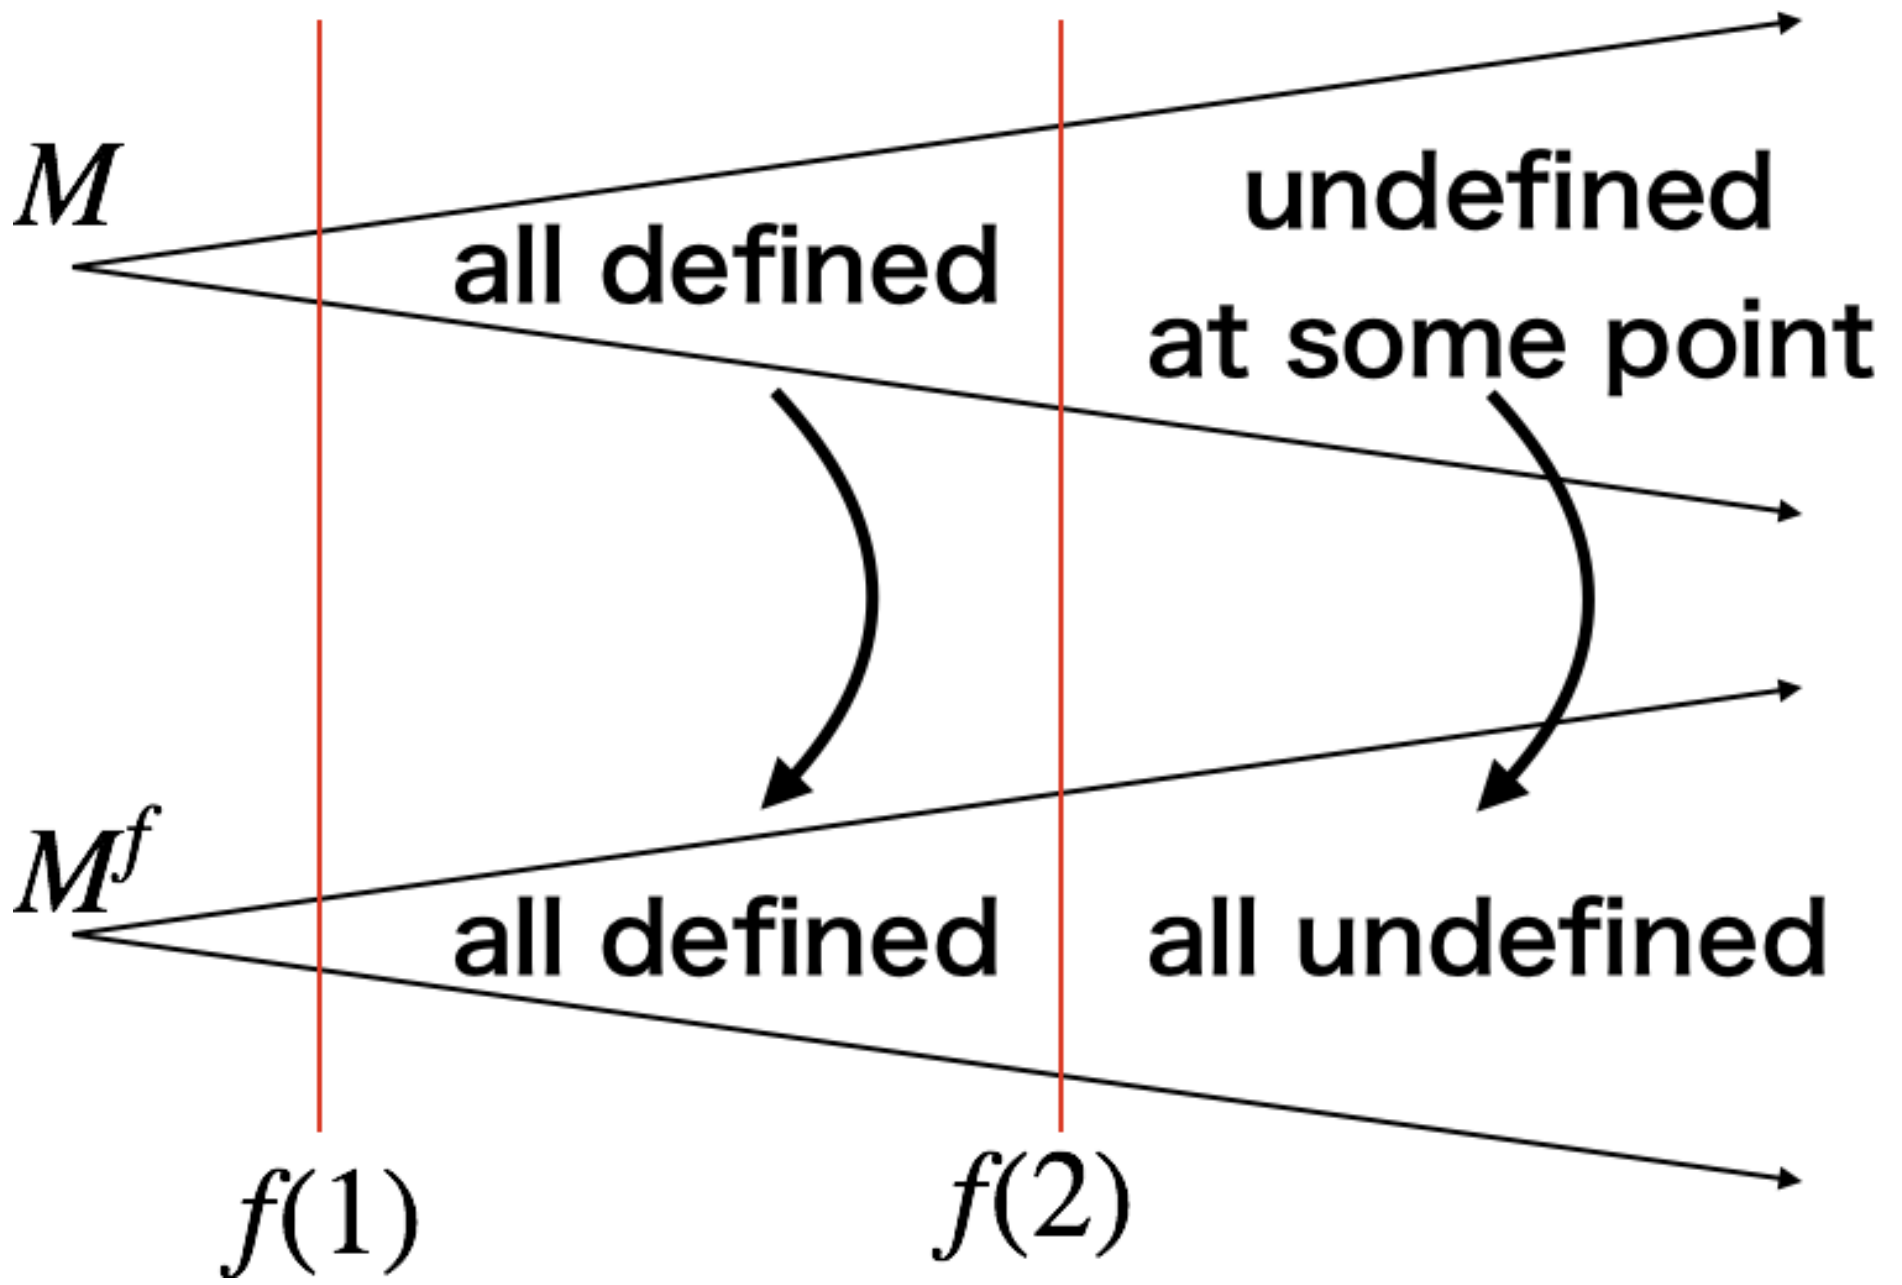

$f$ : a computable order

Modify  $M$  via  $f$  as follows.

$$M^f(\sigma) = \begin{cases} M(\sigma) & \text{if } M(\tau) \downarrow \text{ for all } |\tau| \leq f(n_\sigma) \\ \uparrow & \end{cases}$$

where

$$n_\sigma = \min\{f(k) : k \in \mathbb{N}, |\sigma| \leq f(k)\}$$

# Wait

$M$ : a (maybe partial) computable martingale

$n$ : a natural number

Modify  $M$  via  $n$  as follows.

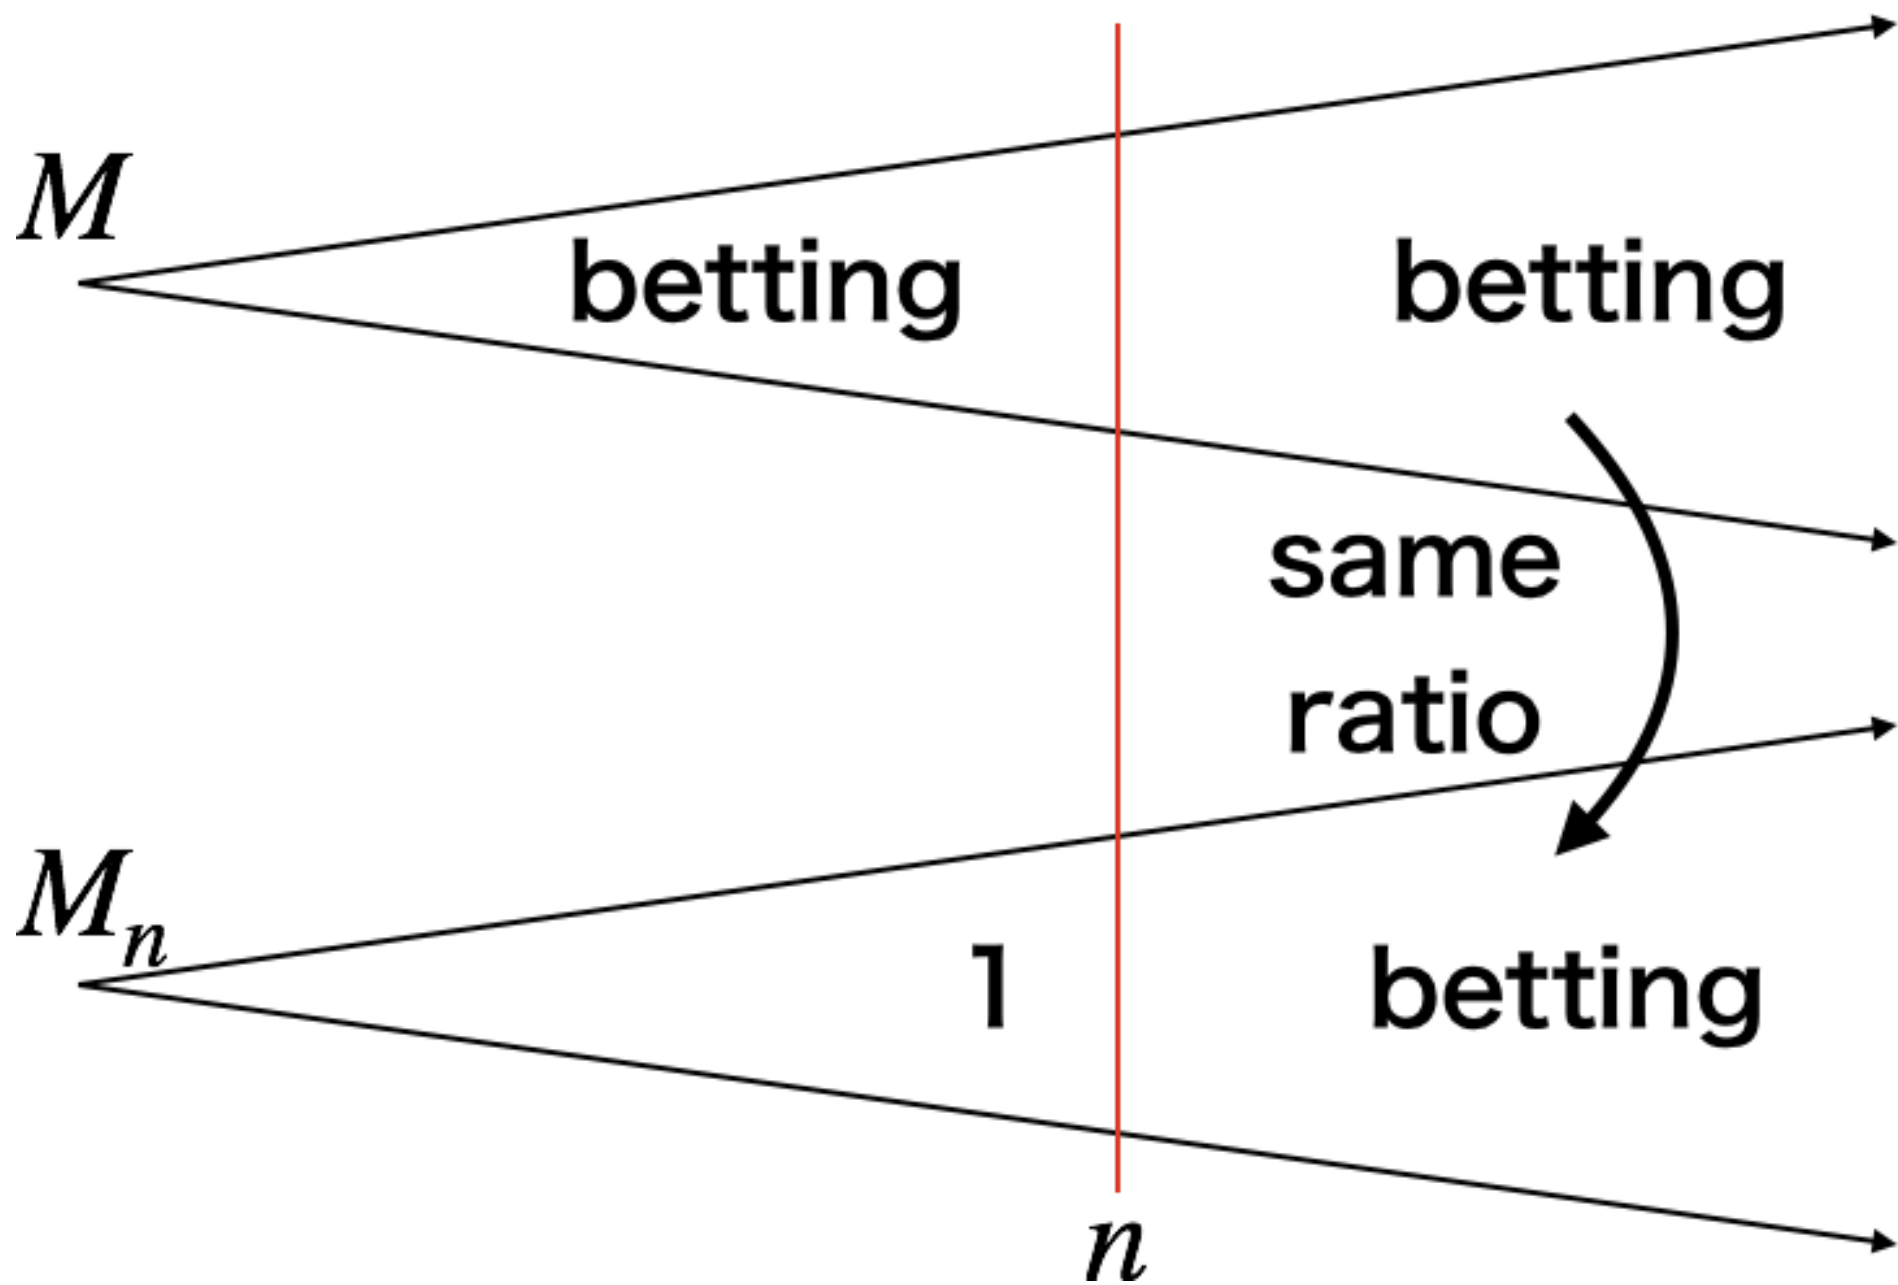

$$M_n(\sigma) = 1 \text{ for } |\sigma| \leq n$$

( $M_n(\sigma)$  is defined even if  $M(\sigma)$  is undefined)

and

$$\frac{M_n(\sigma a)}{M_n(\sigma)} = \frac{M(\sigma a)}{M(\sigma)} \text{ for } |\sigma| \geq n$$

( $M_n(\sigma)$  is undefined if  $M(\sigma)$  is undefined).

## 3rd try

$f$  : a computable order (fast growing)

Define a supermartingale  $M$  by

$$M = \sum_e 2^{-e} M_{e, f(e)}^f$$

$M$  multiplicatively dominates each  $M_{e, f(e)}^f, M_{e, f(e)}, M_e$ .

Define a set  $X$  so that  $M$  does not increase along  $X$ .

To compute  $X \upharpoonright n$ , it suffices to know which  $M_e(\sigma)$  is defined.

The number is roughly  $(f^{-1}(n))^2/2$ , which is much smaller than  $n$ .

$e$	$\langle f(1) \rangle$	$\langle f(2) \rangle$	$\dots$	$\langle f(n) \rangle$
1	1	1	$\dots$	1
2	0	1	$\dots$	1
$\vdots$				
$n$	0	0	0	1

## 3rd try (continued)

Hence,

$$K(X \upharpoonright n) \ll n$$

and  $X$  is not ML-random.

The computation of  $X \upharpoonright n$  is valid only if the input argument is correct.

So we can not replace  $K$  with  $K_M$  for a decidable machine  $M$ .

Construction of  
Schnorr random sets

# Some extension

# *Highness is necessary*

Which degree contains a set  $X \in \text{CR} \setminus \text{MLR}$ ?

**Theorem 5** (Nies-Stephan-Terwijn 2005). *If a set  $X$  is Schnorr random and not high, then  $X$  is already ML-random.*

Recall that  $A$  is **high** if and only if  $A$  computes a function  $f$  that dominates all computable functions.

# *Highness is sufficient*

**Proposition 6.** *Every high set  $A$  computes a computably random set.*

We only care about computable martingales.

$M$ : a computable martingale

$g_M(n)$ : the maximum of time to compute  $M(\sigma)$  with  $|\sigma| \leq n$

Then,  $g_M$  is a computable order.

# *Proof 1*

$\{M_e\}$ : a uniform sequence of all partial computable martingales

Define a supermartingale  $M$  by

$$M(\sigma) = \sum_e 2^{-e} M_{e,e}(\sigma)[f(e + |\sigma|)]$$

Define a set  $X$  so that  $M$  does not increase along  $X$ .

$$X \leq_T M \leq_T f \leq_T A$$

# Proof 2

Suppose  $M_e$  is a total computable martingale.

$f$  dominates  $g_{M_e}$

$\exists e'$  s.t.  $M_e = M_{e'}$  and  $g_{M_{e'}}(n) \leq f(e' + n)$  for all  $n$ .

Since  $\sup_n M(X \upharpoonright n)$  is bounded, so is  $\sup_n M_e(X \upharpoonright n)$ .

Hence,  $X$  is computably random.

# Encode

To construct a computably random set  $X \equiv_T A$ , we use Kučera-Gács coding.

**Theorem 7** (Kučera '85, Gács '86). *Every set is computable from a ML-random set.*

In particular, for each  $A \geq_T \emptyset'$ , there exists a ML-random set  $X \equiv_T A$ .

We skip the details.

By combining all techniques, given a high set  $A$ , we can construct a set  $X \equiv_T A$  s.t.  $X \in \text{CR} \setminus \text{MLR}$ .

# Construction of Schnorr random sets

# Schnorr randomness

$X$  is **computably random** if  $\sup_n M(X \upharpoonright n) < \infty$  for each computable martingale  $M$ .

$X$  is **Schnorr random** if  $M(X \upharpoonright n) < f(n)$  a.a. for each comp. mart.  $M$  and each comp. order  $f$ .

**Proposition 8.** *There exists a Schnorr random set  $X$  that is not computably random.*

We construct a set  $X$  s.t.

- (i) every comp. mart. increases more slowly than a comp. order along  $X$ .
- (ii) some comp. mart. is unbounded along  $X$ .

**sparse**

**X**    1 2 3 4 5 ...     $h(1)$                      $h(2)$

random                                    0 random 0

**M: non-increasing**

**M: at most doubled**

# Mistakes

The function  $h(i)$  should be

- (i) **incomputable** so that any computable martingale grows more slowly than any computable order ( $\Rightarrow$  Schnorr random)
- (ii) **computable in some sense** so that some computable martingale succeeds ( $\Rightarrow$  not computably random)

Idea:

We allow the martingale to make mistakes limited times.

So how many?

# *Martingale*

Martingales can refer to

- (i) a tack used to control horses,
- (ii) a betting strategy,
- (iii) a nonnegative capital process introduced by Ville in 1939 to criticize von Mises,
- (iv) a stochastic process developed by Doob in probability theory

Figure 1: Martingale from wikimedia

# ***Martingale strategy***

Martingale strategy:

Is the next bit 0 or 1?

One starts to bet  $a$  yen on 0 (or 1).

If lost, then doubles their wager.

Almost surely, one will win eventually, after  $k$ -times lost.

The sum of lost capital is

$$a + 2a + 2^2a + \dots + 2^{k-1}a = (2^k - 1)a$$

and they will get  $2^k a$  by the winning,  
so they will gain  $a$  yen.

By iterating this, they will gain infinite sum of money.

This is the **martingale strategy**.

# *Martingale strategy to work*

The martingale strategy does not work in reality.  
The number  $k$  of lost becomes larger a.s.  
With finite initial capital, they will bankrupt eventually.

At  $n$ -th round, one starts to bet  $n^{-1}$ .

If the number of lost is bounded by  $\log n$ , then  
the sum of lost capital is bounded by

$$\frac{2^k - 1}{n} \leq \frac{2^{\log n} - 1}{n} \leq 1$$

By iterating this, one will gain

$$\sum n^{-1} = \infty$$

# Conditions for $n$

The function  $h$  should satisfy the following:

- (i)  $h$  dominates every computable function.
- (ii)  $H(x)$  is the set of the candidates of  $h(x)$ .
- (iii) The relation  $s \in H(x)$  is computable.
- (iv)  $|H(x)| \leq \log x$ .

We construct such a function  $n$  by modifying the busy beaver function.

# *Busy beaver function*

The **busy beaver function**  $BB(x)$  can be defined by

$$BB(x) = \max\{s : U(\sigma) \downarrow \text{ at } s, |\sigma| \leq x\}$$

where  $U$  is a universal Turing machine.

$$H(x) = \{s : U(\sigma) \downarrow \text{ at } s, |\sigma| \leq x\}$$

can be the set of the candidates,  
and  $s \in T(x)$  is a computable relation,  
but  $|H(x)|$  seems larger than  $\log x$ .

# Modified BB function

$$H(x) = \{ \langle e, x, s \rangle + 1 : \Phi_e(x) \downarrow \text{ at } s, e < \log p(x) - 1 \}$$

and

$$h(x) = \max\{T(x)\}$$

where  $p$  is comp. with  $p(x) \leq x$ .

$h$  dominates all computable functions.

$t \in H(x)$  is a computable relation.

$$|H(x)| \leq \log p(x) - 1.$$

At  $p(x)$ -th round,  $H(x)$  will be used.

By filling the gap, we conclude  $\exists X \in \text{SR} \setminus \text{CR}$ .

# Summary

- We gave a proof idea of  $\exists X \in \text{CR} \setminus \text{MLR}$ .
- The key ideas are to **enumerate**, **unite** and **wait**.
- **Highness** is the necessary and sufficient degree to compute such sets.
- The Kučera-Gács coding allows us to compute the converse.
- We gave a proof idea of  $\exists Y \in \text{SR} \setminus \text{CR}$ .
- The key notions are modified versions of the **martingale strategy** and the **busy beaver function**.

# *End*

Thank you.
